SUMMARY

Arrhythmogenic right ventricular dysplasia (ARVD) is both a myocardial disease that predominantly affects the right ventricle (RV) and one of the major causes of sudden death in the young and athletes. A 28-year-old man with no significant medical history, applied to an emergency department with feeling very ill. After his initial examinations, electrocardiography (ECG) showed ventricular extra systoles and he was recommended for admission to a cardiology polyclinic. The next day, his condition worsened and he was dead on arrival at the hospital. A histological examination of heart samples, which were obtained from the RV and LV, revealed the massive replacement of myocardium by fibrous and mature adipose tissue in the RV. In this case, there were no symptoms, family and medical history and its clinical presentation was as an unexpected sudden death.

Keywords: Arrhythmogenic right ventricular dysplasia, sudden cardiac death, autopsy

Úmrtí v důsledku arytmogenní dysplasie pravé komory srdeční: Kazuistika

SOUHRN

Arytmogenní dysplasie pravé komory srdeční je jednou z hlavních příčin náhlého úmrtí mladých sportovců. V práci je popisován případ mladého muže, který zemřel ve 28 letech bez jakýchkoliv anamnestických příznaků. Při příjezdu na pohotovostní příjem se cítil velmi špatně. První vyšetření EKG vykazovalo ventrikulární extrasystoly a bylo proto doporučeno přijetí na kardiologickou kliniku. Následující den se jeho stav natolik zhoršil a na tuto kliniku byl přivezen již mrtev. Histologické vyšetření vzorků srdeční svaloviny odebrané z pravé i levé komory odhalilo masivní přeměnu svaloviny pravé komory ve fibrózní a vyzrálou tukovou tkáň. V tomto případě šlo o náhlé úmrtí bez přítomnosti jakýchkoliv symptomů či rodinné nebo osobní anamnézy.

Klíčová slova: arytmogenní dysplázie pravé komory – náhlá srdeční smrt – pitva

Soud Lek 2013; 58(3): 39–41

Arrhythmogenic right ventricular dysplasia (ARVD) is one of a number of sudden death causes among the young and athletes (1,2). ARVD is a myocardial disease, affecting the right ventricle (RV), morphologically characterized by diffuse or segmental lack of myocardium in the RV free wall, which is replaced by fatty or fibro fatty tissue, and also histologically by fibro fatty degeneration of cardiomyocytes, which leads to electrical instability and contractility abnormalities (1,3–9). We described an autopsy case of a 28-year old man with sudden death due to ARVD.

CASE REPORT

A 28-year-old man with no significant medical history applied to the emergency department of provincial hospital with feeling very ill. An electrocardiography (ECG) performed in the emergency department the day before he died showed ventricular extra systoles as well as ventricular arrhythmia. After his initial physical examination, he was recommended for admission to a cardiology polyclinic for detailed investigation. The next day, his condition worsened and he was dead on arrival at the hospital. A medico-legal autopsy was performed to clarify the manner and cause of death as mandated by the local prosecutor. His clinical history was completely inconspicuous and his family history had no indication sudden cardiac death. An external examination showed that deceased was 182 cm in height and weighed 90 kg. White foam around the mouth and nostrils, injection marks on the inguinal and antecubital regions and the dorsal part of left hand as well as signs of defibrillation paddles on the anterior wall of the chest were detected during external examination. No significant injuries were observed on external examination. At gross macroscopic internal examination, the heart weighted 560 g, the heart chambers appeared dilated and petechial hemorr-

hages were observed on the surface of the LV (Figure 1). Dissection of right ventricular wall revealed a yellowish discoloration of fat tissue. The sections of left ventricular wall and septum were normal in macroscopic investigation. There were only non-specific signs, such as organ congestion, and pulmonary oedema as the pathological macroscopic findings of internal organs. Histological sections of formalin-fixed tissue from the brain, cerebellum, lungs, liver, kidneys, and spleen revealed nonspecific postmortem findings. Pathologic investigation included hematoxylin-eosin, Mason-Trichrome staining and CD8, CD4 immunostaining. The slides were examined with a light microscope. Sections from the heart which were obtained from the RV and LV. Samples from RV revealed massive replacement of myocardium by fibrous and mature adipose tissue in the right ventricle (Figure 2). The predominance of CD4+ and CD8+ lymphocytes were observed microscopically. The gross and microscopic examinations were otherwise unremarkable.

A toxicological screening of tissue was performed and blood and urine samples were taken. The Headspace Gas Chromatography (GC/HS) technique was used for blood alcohol analysis which was at normal levels and Spot Test, Thin Layer Chromatography (TLC) and Cloned Enzyme Donor Immunoassay (CEDIA) techniques were used for drug screening in tissue, blood and urine samples which were negative for analyzed substances.

DISCUSSION

Arrhythmogenic right ventricular dysplasia (ARVD) is a myocardial disease, which predominantly affects the right ventricle (RV) and is one of the major causes of sudden death in the young and athletes (1,2). ARVD is morphologically characterized by diffuse or segmental lack of myocardium in the RV free wall which is replaced by fatty or fibro fatty tissue and also histologically by fibro fatty degeneration of cardiomyocytes which leads to electrical instability and contractility abnormalities (1,3-8). The replacement of the right ventricular myocardium by fibro fatty tissue is progressive process, starting from the epicardium or midmyocardium and then extending to become transmural pathology (2,9). Although several theories have been proposed and different genetic variants have been described, the accurate aetiopathogenesis of ARVD is still unknown (2-5,7-10). ARVD has been described as a disease of unknown cause, characterized by fibro fatty replacement of the RV myocardium (7). The diagnosis of ARVD is based on major and minor criteria including

genetic, structural, histological, electrocardiographic, and familial factors which have been established by the Study Group on ARVC of the Working Group Myocardial and Pericardial Disease of the European Society of Cardiology and of the Scientific Council on Cardiomyopathies of the International Society and Federation of Cardiology (8,10). However, many of the cases, of which the first clinical presentation was sudden death, were diagnosed with an autopsy similar to our presented case. Sporadic and familial forms of the ARVD have been described (11). The presence of a family history of ARVD has been reported in 30 % to 50 % of cases (2,5,12,13,15). The autosomal dominant is the most common inheritance form of ARVD, although autosomal recessive forms like Naxos Disease and Carvajal Syndrome have also been reported in the literature (5,14,15). Twelve different genetic variants have been described associated with ARVD, resulting from mutations of genes encoding several components of cardiac desmosomes (15,16). ARVD is associated with highly variable clinical presentation such as ventricular tachycardia, syncope, RV dysfunction and sudden death (2,5,7,8,9). In the 7 % to 29 % of the cases, the first presentation of ARVD may be sudden cardiac death with no prior onset symptoms (15,17). In the presented case there were no symptoms, family and medical history and his first clinical presentation was unexpected sudden death. For that reason, an autopsy is essential to reveal the exact morphologic and histopathologic features of the disease and to provide a proper explanation of the cause of sudden death. Fatty and fibro fatty forms are the two morphologic variants of ARVD (8). While the residual islands of myocytes are surrounded by fibrosis, RV wall thinning with aneurysmal dilatation, mononuclear inflammatory cell infiltrates and involvement of LV and septum in some cases are seen in the fibro fatty form, the fatty form is characterized by an almost complete replacement of myocardium by adipose tissue with sparing of the septum and left ventricle and without wall thinning (4,7). In this present study, a case of the morphologically fibro fatty form of ARVD without involvement of LV and septum was described. Microscopic evaluation revealed CD8+ lymphocytes on the RV myocardial samples. Thiene G et al. reported that myocardial inflammation may be seen in up to 75 % of hearts at autopsy (18). However, these findings to date have not been clearly understood and explained as to whether inflammation is cause of the cell death or a response to primary myocardial changes (is it a cause or consequence in reality?). We presented interesting autopsy case of ARVD whose first clinical presentation was sudden unexpected death.

ZPRÁVY Z KONFERENCE

Expert Forensic Science 25. 1. – 26. 1. 2013

Ve dnech 25. 1. a 26. 1. 2013 proběhl v Brně již 22. ročník mezinárodní vědecké konference soudního inženýrství pro znalce v technických a ekonomických oborech ExFoS (Expert Forensic Science) 2013. Pořadatelem akce byl Ústav soudního inženýrství VUT Brno ve spolupráci s Asociací znalců a odhadců České republiky (AZO) a Evropskou společností pro výzkum a analýzu nehod - Národní skupinou ČR (EVU). Přednášky byly rozděleny do čtyř sekcí, kdy z pohledu soudního lékaře nejzajímavější sekce - Analýza silničních nehod obsahovala asi 20 příspěvků, vesměs orientovaných na nejnovější poznatky vědy a výzkumu v této oblasti. Nedílnou součástí byl i společenský večer ve stylové restauraci, kde zazněla četná zajímavá sdělení, pro která nezbyl prostor na oficiálním fóru konference.
